Abstract

We establish the incompressible Navier–Stokes limit for the discrete velocity model of the Boltzmann equation in any dimension of the physical space, for densities which remain in a suitable small neighborhood of the global Maxwellian. Appropriately scaled families solutions of discrete Boltzmann equation are shown to have fluctuations that locally in time converge strongly to a limit governed by a solution of Incompressible Navier–Stokes provided that the initial fluctuation is smooth, and converges to appropriate initial data. As applications of our results, we study the Carleman model and the one-dimensional Broadwell model.

1 Introduction and Main results

1.1 Introduction

The endeavor to understand how fluid dynamical equations can be derived from kinetic theory goes back to the founding works of Maxwell [38] and Boltzmann [16]. Most of derivations are well understood at several formal levels by now, and yet their full mathematical justifications are still missing. Here we establish a so-called incompressible Navier–Stokes fluid dynamical limit for the discrete Boltzmann equation which is an evolution model for a gas which can attain only a finite number of velocities, one has to mention that Inoue and Nishida [30], and Caflish and Papanicolaou [19] have developed an asymptotic theory for the six velocity Broadwell’s model. Further Studies have been developed for the two velocity Carleman’s model by Kurtz [33] and by Lions and Toscani [36]. The interested reader can recover the pertinent literature in the survey by Lachowicz [34].

As known, see Bonilla and Soler [14], different asymptotic expansions can be developed for kinetic models thus obtaining various hydrodynamic descriptions. It has been recently recognized by several mathematicians, Bardos, Golse and Levermore [3, 4], Demasi, Esposito and Lebowitz [21], that the incompressible Navier–Stokes equation can be obtained as the limit of the Boltzmann equation, when the Knudsen number $\varepsilon > 0$ go to zero. The validity of this fluid-dynamical approximation have been studied by several authors, see [2, 5, 6, 10, 21, 25, 26, 37]. On the other hand, there is non proof concerning the convergence...

of discrete velocity kinetic models to a solution of the incompressible Navier–Stokes equations. However, although a complete proof is not given, some partial results may be found in [9, 10, 11, 28] in particular for Carleman and Broadwell’s models. In the present paper a rigorous proof of the connection between these two points of view is done, precisiong and completing some results which were announced in [4].

Let \( \varepsilon > 0 \) be the Knudsen number, and consider the scaled discrete Boltzmann equation

\[
\varepsilon \partial_t F_i + v_i \cdot \nabla_x F_i = \frac{1}{\varepsilon} Q_i(F, F), \quad i = 1, \ldots, m,
\]  

(1.1)

where \( F_i = F_i(t, x) \) represents the mass density of gas particles with the constant velocity vector \( v_i = (v_{i1}, \ldots, v_{in}) \in \mathbb{R}^n \) at time \( t \geq 0 \) and position \( x = (x_1, \ldots, x_n) \in \mathbb{R}^n \); \( Q_i \) is a quadratic operator related to the binary collisions:

\[
Q_i(F, G) = \frac{1}{2\alpha_i} \sum_{jkl} \left\{ A_{ij}^{kl}(F_kG_l + F_lG_k) - A_{kl}^{ji}(F_iG_j + F_jG_i) \right\},
\]  

(1.2)

where \( \alpha_i \) are positive constants, and the terms \( A_{ij}^{kl} \) are the so-called transition rates referring to the collisions

\[
(v_i, v_j) \leftrightarrow (v_k, v_l).
\]

The transition rates are positive constants which, according to the indistinguishability property of the gas particles and the reversibility of the collisions, fulfill the following properties:

\[
A_{ik}^{ij} = A_{jk}^{ij} = A_{jl}^{ij} = \cdots = A_{kl}^{ij}.
\]  

(1.3)

A detailed computation of the terms \( A_{ij}^{kl} \) can be performed by specializing the velocity discretization and analyzing the related collision mechanics.

The above mathematical structure includes, as particular applications, various mathematical models of discrete Boltzmann equation which can be recovered in the pertinent literature [18, 23]. It also refers to models with arbitrarily large number of velocities which have been studied in a number of recent papers, see among others [1, 27], considering their relatively simpler structure, with respect to the full Boltzmann equation, which may be exploited for scientific computing. Indeed, convergence to the full Boltzmann equation can be studied for models with arbitrary large number of velocities.

Following [7, 18, 23], we shall introduce the basic concepts concerning (1.1) and summarize their properties which will be used later.

**Definition 1.** A vector \( \phi = t(\phi_1, \ldots, \phi_m) \in \mathbb{R}^m \) is called a summational invariant if

\[
A_{kl}^{ij} \left( \frac{\phi_i}{\alpha_i} + \frac{\phi_j}{\alpha_j} - \frac{\phi_k}{\alpha_k} - \frac{\phi_l}{\alpha_l} \right) = 0,
\]

for all \( i, j, k, l = 1, \ldots, m \).

We denote by \( M \) the set of summational invariants. Then \( 0 < \dim M < m \) because \( t(\alpha_1, \ldots, \alpha_m) \in M \) and \( M \neq \mathbb{R}^m \). The following three conditions are equivalent:
\[ \phi \in \mathbb{M}, \]
\[ \langle \phi, Q(F, G) \rangle = 0 \text{ for all } F, G \in \mathbb{R}^m, \]
\[ \langle \phi, Q(F, F) \rangle = 0 \text{ for all } F \in \mathbb{R}^m. \]

Here \( \langle \cdot, \cdot \rangle \) denotes the standard inner product in \( \mathbb{R}^m \). For the proof see [7, 18, 23].

Let \( F = t(F_1, \ldots, F_m) \in \mathbb{R}^m \). We write \( F > 0 \) if \( F_i > 0 \) for all \( i = 1, \ldots, m \).

**Definition 2.** A vector \( F = t(F_1, \ldots, F_m) > 0 \) is called a local Maxwellian if

\[ A_{kl}^{ij}(F_i F_j - F_k F_l) = 0, \quad \text{for all } i, j, k, l = 1, \ldots, m. \]

In particular, \( F > 0 \) is called an absolute Maxwellian if it is a locally Maxwellian state and is independent of \( t \) and \( x \).

Consider the initial value problem for Eq. (1.1):

\[
\varepsilon \partial_t F_\varepsilon + \sum_{j=1}^n V^j \partial_{x_j} F_\varepsilon = \frac{1}{\varepsilon} Q(F_\varepsilon, F_\varepsilon), \quad t > 0, \quad x \in \mathbb{R}^n,
\]
\[ F_\varepsilon(0, x) = F_0(x), \quad (1.4) \]

where

\[ V^j = \text{diag}(v_1^j, \ldots, v_m^j), \quad j = 1, \ldots, n, \]

and

\[ Q(F, G) = t(Q_1(F, G) \ldots Q_m(F, G)). \]

According to [4], the discrete velocity Boltzmann equation (1.1) gives the incompressible Navier–Stokes equation in the limit \( \varepsilon \to 0 \) if \( F_\varepsilon \) remains near an absolute Maxwellian \( M \) with the distance of order \( \varepsilon \).

Let \( M > 0 \) be an absolute Maxwellian state, and let

\[ \Lambda = \text{diag} \left( \frac{M_1}{\alpha_1}, \ldots, \frac{M_m}{\alpha_m} \right). \]

We shall see the solution in the form

\[ F_\varepsilon(t, x) = M + \varepsilon \frac{1}{2} \Lambda f_\varepsilon. \]

Then Problem (1.4) can be transformed into the following one:

\[
\partial_t f_\varepsilon + \frac{1}{\varepsilon} \sum_{j=1}^n V^j \partial_{x_j} f_\varepsilon + \frac{1}{\varepsilon^2} L f_\varepsilon = \frac{1}{\varepsilon} \Gamma(f_\varepsilon, f_\varepsilon),
\]
\[ f_\varepsilon(t = 0, x) = f_0(x) = \Lambda^{-\frac{1}{2}} (F_0(x) - M), \quad (1.5) \]

where the operators \( L \) and \( \Gamma \) are given by

\[ Lf = -2\Lambda^{-\frac{1}{2}} Q \left( M, \Lambda^{\frac{1}{2}} f \right), \quad (1.6) \]
\[ \Gamma(f, g) = \Lambda^{-\frac{1}{2}} Q \left( \Lambda^{\frac{1}{2}} f, \Lambda^{\frac{1}{2}} g \right), \quad (1.7) \]

and have (see [7, 18, 23]) the following properties:
(i) $L$ is real symmetric and positive semi-definite. It is null space is given by $N(L) = \Lambda^\perp \mathbb{M}$. We denote by $\{e_i, i = 1, \ldots, d\}$ the orthonormal basis for $N(L)$.

(ii) $\Gamma$ is bi-linear and satisfies $\Gamma(f, g) \in N(L)^\perp$ for any $f, g \in \mathbb{R}^m$, where $N(L)^\perp$ denotes the orthogonal complement of $N(L)$ in $\mathbb{R}^m$.

Existence of global solutions for discrete kinetic models have been obtained by several authors (see [15, 17] and the review article of Bellomo and Gustafsson [8]). However these results cannot be used here because they are based on the dispersion properties of the linearized equations and concern small (with respect to the collision operator) perturbations of the vacuum. It is easy to prove that any finite velocity model has a unique smooth solution during a finite time that depends on the size of the initial data and on the collision operator (or a global existence see [31, 32]). To the best of our knowledge it has not been proven that the time of existence of this smooth solution is independent of $\varepsilon$.

Now we state our main results.

### 1.2 Main results

Our main result is an existence theorem that holds for all $\varepsilon > 0$ and a proof of the validity of the fluid-dynamical approximation. To state our result precisely, one needs some function spaces.

Let $C(\Omega, X)$ and $L^\infty(\Omega, X)$ denote the spaces of the continuous and bounded functions on $\Omega \subset \mathbb{R}^n$ with values in a Banach space $X$, respectively.

$H^l$ denotes the $L^2(\mathbb{R}^n)$-Sobolev space of order $l$, with the norm $\| \cdot \|_l$.

**Theorem 1.** Let (1.3) be assumed. Let $n \geq 1$ and $l \geq \frac{n}{2}$. If $f_0 \in H^l(\mathbb{R}^n)$, then there exists a positive constants $T_0$ and $k$ (depending only on $\|f_0\|_l$) such that the initial value problem (1.5) has a unique solution $f_\varepsilon \in L^\infty([0, T_0], H^l) \cap C([0, T_0], H^{l-1}(\mathbb{R}^n))$ satisfying

$$\|f_\varepsilon(t)\|_l \leq k,$$

for $t \in [0, T_0]$.

If, in addition the initial data satisfies:

$$f_\varepsilon(0) = h_\varepsilon + \varepsilon^2 k_\varepsilon \quad \text{where} \quad k_\varepsilon \in H^l \quad \text{and},$$

$$h_\varepsilon \in N(L), \quad \|\Gamma(h_\varepsilon, h_\varepsilon)\|_{l-1} \leq C\varepsilon, \quad \|\partial_x h_\varepsilon\|_{l-1} \leq C\varepsilon,$$

$$\lim_{\varepsilon \to 0} \|h_\varepsilon - h\|_{l-1} = 0.$$  \hspace{1cm} (1.9)

one gets the strong convergence for the discrete Boltzmann equation to Incompressible Navier–Stokes equations:

**Theorem 2.** Let $f_\varepsilon$ be as in Theorem 1. Then, as $\varepsilon \to 0$, $f_\varepsilon \rightharpoonup f$ weakly $\star$ in $L^\infty([0, T], H^l)$ and strongly in $C([0, T], H^{l-1})$ for any $T > 0$, and the limit has the form

$$f = \sum_{i=1}^d \rho_i e_i,$$  \hspace{1cm} (1.10)
where \( \rho_i = \langle e_i, f \rangle \) satisfy:
\[
\nabla_x \cdot (V e \otimes e \cdot \rho) = 0.
\]

(1.11)

Moreover, \( \rho(t, x) \) is a weak solution of the equations:
\[
\begin{align*}
\frac{\partial \rho}{\partial t} - \nabla^2 : \langle (L^{-1}(P^\perp(V e)) \otimes (V e) \rangle \cdot \rho + \frac{1}{2} \nabla \cdot \langle P^\perp(V e) \rangle \left( \frac{\rho \cdot e}{\sqrt{\alpha M}} \right)^2 &= \langle V \cdot \nabla e \otimes e \rangle \cdot \pi, \\
\rho(t = 0) &= \langle h, e \rangle,
\end{align*}
\]

(1.12)

where \( \frac{\sigma^2}{\sqrt{\alpha M}} \) denotes the vector \( \left( \frac{\sigma_1^2}{\sqrt{\alpha_1 M_1}}, \ldots, \frac{\sigma_n^2}{\sqrt{\alpha_n M_n}} \right) \) and the vectors
\[
\begin{align*}
\nabla^2 : \langle V e \otimes L^{-1}(P^\perp(V e)) \rangle \rho \quad \text{and} \quad \nabla \cdot \langle P^\perp(V e) \rangle \left( \frac{\rho \cdot e}{\sqrt{\alpha M}} \right)^2
\end{align*}
\]

are given by:
\[
\begin{align*}
\nabla^2 : \langle V e \otimes L^{-1}(P^\perp(V e)) \rangle \rho &= \left( \sum_{j=1}^n \sum_{k=1}^n \partial_{x_j} \partial_{x_k} \langle V^k \rho \cdot e, L^{-1} \left( P^\perp(V^j e_i) \right) \rangle \right)_{i}, \\
\nabla \cdot \langle P^\perp(V e) \rangle \left( \frac{\rho \cdot e}{\sqrt{\alpha M}} \right)^2 &= \left( \sum_{j=1}^n \partial_{x_j} \left( \frac{\rho \cdot e}{\sqrt{\alpha M}}, P^\perp(V^j e_i) \right) \right)_{i}.
\end{align*}
\]

Let \( (\rho_\varepsilon)_i = \langle e_i, f_\varepsilon \rangle \). Since \( \{e_i, i = 1, \ldots, d\} \) forms an orthogonal system, \( \rho \) in (1.10) is given by \( \rho_i = \langle e_i, f \rangle \). One gets

\textbf{Theorem 3.} Let (1.9) be assumed. Then, as \( \varepsilon \to 0 \), \( \rho_\varepsilon \to \rho \) weakly \( \ast \) in \( L^\infty([0, T], H^1) \) and strongly in \( C([0, T], H^{1-1}) \) for any \( T > 0 \), and the limit \( \rho \) satisfies the incompressible Navier–Stokes equations (1.11)–(1.12).

The system (1.11)–(1.12) are generalizations of the Navier–Stokes equations. The condition (1.11) generalizes the \( \nabla \cdot u = 0, \nabla (\rho + \theta) = 0 \) conditions that arise in the classical incompressible Navier–Stokes limit (see [3]). \( \pi \) is the lagrange multiplier corresponding to the constraint (1.11) and is the generalization of the classical pressure term. The quadratic term in (1.12) corresponds to the classical convection terms. The justification of these formal approximations for the classical Boltzmann equation has proven difficult because many regularity questions remain open for both these fluid systems as the Boltzmann equation. Two approaches to circumventing these difficulties have emerged recently. First some authors have studied direct derivations of linear or weakly nonlinear fluid dynamical systems, such as incompressible Navier–Stokes [21]. Their result requires smooth initial data and holds for as long as the limiting solution of the incompressible Navier–Stokes system is smooth. Second, some authors have abandoned the traditional expansion-based derivations in favor of moments based formal derivation [5, 6, 26]. In [6] it is shown that the solution of the Boltzmann equation considered over space of dimension three or more will be smooth for all time, with small initial data and will converge strongly to the solution of the incompressible Navier–Stokes equations. Recently the Incompressible Navier–Stokes fluid dynamical limit for the classical Boltzmann equation is considered.
The incompressible Navier–Stokes for the Non Linear Discrete Velocity Models

in [26]. It was shown that the scaled families of DiPerna–Lions renormalized solutions [22] have fluctuations that globally in time converge weakly to a limit governed by a solution of the incompressible Navier–Stokes equations due to Leray [35] provided that

\[ H(f_\varepsilon(0)) = \int \int_{\mathbb{R}^3 \times \mathbb{R}^3} (f_\varepsilon(0) \log f_\varepsilon(0) - f_\varepsilon(0) + 1) M \, dv \, dx \leq C\varepsilon^2, \]

and the fluid moments of their initial fluctuations converge to appropriate \( L^2 \) initial data. The proof use the averaging lemma (cf. [24]). The averaging lemma is valid for continuous solutions and has no counterpart for discrete velocity models (except in one space dimension (cf. Tartar [39])). However, in the proof of Theorem 2, one needs to evaluate the limit of the nonlinear moment

\[ \langle L^{-1}(P(V_\varepsilon)), \Gamma(f_\varepsilon, f_\varepsilon) \rangle. \quad (1.13) \]

Some uniform regularity estimates would likely be needed for obtaining the limit of nonlinear terms (1.13). This term disappears in the case of Stokes limit (see [12]).

Here we establish a so-called incompressible Navier–Stokes fluid dynamical limit (1.11)–(1.12) for the discrete Boltzmann equation in any dimension of the physical space. We solve (1.5) by using the principle of contraction mappings, we introduce the iteration scheme (Lemma 1 and Lemma 2) similar to one used in [19] to obtain the uniform estimate of the remainder term in the Hilbert expansion in order to justify the compressible Euler system from the one dimensionnal Broadwell. The convergence of the scheme to a solution of equation (1.5) is proved by using some properties of the operators \( L \) and \( \Gamma \). The strong convergence of the solution of equation (1.5) as \( \varepsilon \to 0 \) is proved by the uniform estimate and the equicontinuity in \( t \in [0, T] \) of the solution with respect to \( \varepsilon \in (0, 1) \) (Lemma 3) provided that the initial fluctuation is smooth, close to an \( N(L) \) element which converges to appropriate initial data.

**Remark 1.** Put \( h_\varepsilon = \Lambda^{\frac{1}{2}} t_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} w_\varepsilon \), one gets

\[ \Gamma(h_\varepsilon, h_\varepsilon) = w_\varepsilon^2 \Lambda^{-\frac{1}{2}} Q(M, M) = 0. \quad (1.14) \]

An example of assumptions (1.9) can be given by:

\[ f_\varepsilon = \Lambda^{\frac{1}{2}} t_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} w_\varepsilon + \varepsilon^2 k, \]
\[ \| \partial_x w_\varepsilon \|_{l-1} \leq C\varepsilon, \quad \lim_{\varepsilon \to 0} \| w_\varepsilon - w \|_{l-1} = 0. \quad (1.15) \]

**Remark 2.** In the case where \( \frac{h^2}{\sqrt{\alpha M}} \in N(L) \), one has \( \Gamma(h_\varepsilon, h_\varepsilon) = 0 \) (see Lemma 5). Therefore another example can be given by:

\[ f_\varepsilon(0) = h_\varepsilon + \varepsilon^2 k_\varepsilon, \quad \text{where} \quad k_\varepsilon \in H^l \quad \text{and,} \]
\[ h_\varepsilon \in N(L), \quad \frac{h^2}{\sqrt{\alpha M}} \in N(L), \quad \| \partial_x h_\varepsilon \|_{l-1} \leq C\varepsilon, \quad \lim_{\varepsilon \to 0} \| h_\varepsilon - h \|_{l-1} = 0. \]

**Remark 3.** In [12] it was proven that the kinetic models (1.1) converge weakly and strongly to the linearized incompressible Navier–Stokes. The assumption \( \Gamma(h_\varepsilon, h_\varepsilon) = O(\varepsilon) \) in \( H^{l-1} \) is not necessary in this case and the time of existence of solutions goes to infinity as \( \varepsilon \to 0 \).
Remark 4. The present work improves upon the result given in [12] for the Carleman and Broadwell’s model, without assuming some restriction upon the scaling of the fluctuation with respect to Knudsen number, namely that the fluctuations should only be required to be of an order equal to the Knudsen number, but at the cost of being restricted to initial fluctuations (assuming $\Gamma(h_\varepsilon, h_\varepsilon) = O(\varepsilon)$ in $H^{l-1}$) for the Broadwell model.

The plan of this paper is as follows. Section 1 deals with the above introduction and main results. In Section 2, the formulation of the problem and the proof of uniform existence Theorem are given. In Section 3, the estimate for $\partial_t f_\varepsilon$ is shown. This estimate is used to prove the strong convergence of the solution to the solution of the non-linear incompressible Navier–Stokes equation. Finally, Sections 4 and 5 contain some applications. As applications of our results, we are dealt with the Carleman model and the one-dimensional Broadwell model.

2 Uniform existence

To prove the existence of local solutions to (1.5), one has to get suitable “apriori” estimate.

2.1 Estimates

Lemma 1. Let $z(t, x)$ be a given function of $t$ and $x$ such that,

$$\|z(t)|_t \leq k,$$

and let $f(t, x)$ satisfy the linear system

$$\partial_t f + \frac{1}{\varepsilon} \sum_{j=1}^n V_j \partial_{x_j} f + \frac{1}{\varepsilon^2} L f = \frac{1}{\varepsilon} \Gamma(z, f),$$

$$f(0, x) = f_0(x).$$

Then there exist $T_0$ such that a constant $k$ can be chosen such that

$$\sup_{0 \leq t \leq T_0} \|f(t)|_t \leq k.$$  

Proof. From the theory of linear hyperbolic systems we know that (2.2) has a unique solution in $L^\infty([0, T], H^l)$ with $\frac{df}{dt}$ in $L^\infty([0, T], L^2)$. X-Mozilla-Status: 0000

Taking the Fourier transform of (2.2) in $x$ yields

$$\partial_t \hat{f} + \frac{1}{\varepsilon} \sum_{j=1}^n V_j \zeta_j \hat{f} + \frac{1}{\varepsilon^2} L \hat{f} = \frac{1}{\varepsilon} \hat{\Gamma}(z, f).$$

Take the inner product (in $\mathbb{C}^m$) of (2.4) with $\hat{f}$. Since $\sum_{j=1}^n V_j \zeta_j$ and $L$ are real symmetric, the real part of (2.4) is

$$\frac{\partial_t |\hat{f}|^2}{2} + \frac{1}{\varepsilon^2} \langle L \hat{f}, \hat{f} \rangle = \frac{1}{\varepsilon} \text{Re} \langle \hat{\Gamma}(z, f), \hat{f} \rangle,$$

where

$$\langle L \hat{f}, \hat{f} \rangle = \frac{1}{\varepsilon} \text{Re} \langle \hat{\Gamma}(z, f), \hat{f} \rangle.$$
where $\langle \cdot, \cdot \rangle$ denotes the standard inner product in $\mathbb{C}^m$.

Noting that $L$ is positive semi-definite and $\Gamma \in N(L)^\perp$, one obtains due to (2.5) and to the the inequality $ab \leq \frac{1}{2} (a^2 + b^2)$, the following estimate:

$$\frac{\partial_t |\hat{f}|^2}{2} + C_1 \frac{|P^\perp \hat{f}|^2}{\varepsilon} \leq \frac{1}{2C_1} \frac{\hat{\Gamma}(z, f)}{\varepsilon}^2 + \frac{C_1}{2\varepsilon^2} |P^\perp \hat{f}|^2,$$

where $C_1$ is a constant and $P^\perp$ is the orthogonal projection onto $N(L)^\perp$.

In particular (2.6) implies that

$$\frac{\partial_t |\hat{f}|^2}{2} \leq \frac{1}{2C_1} |\hat{\Gamma}(z, f)|^2.$$  

(2.7)

Noting that for $l > \frac{n}{2}$,

$$\|\hat{\Gamma}(f, g)\|_l \leq C_2 \|f\|_l \|g\|_l \quad \forall f, g \in H^l.$$  

(2.8)

So by multiplying (2.7) by $(1 + |\xi|^2)^l$, integrating over $[0, t] \times \mathbb{R}^n$ and using (2.8). One obtains from Plancherel’s Theorem, the following inequality:

$$\|f\|_l^2 \leq \|f_0\|_l^2 + \frac{C_2^2}{C_1} \int_0^t \|f(s)\|^2 l \|z(s)\|^2 ds \leq \|f_0\|_l^2 + Ck^2T \sup_{t \in [0, T]} \|f(t)\|_l^2,$$

(2.9)

with $C = \frac{C_2^2}{C_1}$.

Let $T_0$ and $k$ are such that

$$T_0 = \frac{1}{16C\|f_0\|_l^2}, \quad k = \frac{1 - \sqrt{1 - 4\sqrt{CT}\|f_0\|_l}}{2\sqrt{CT}},$$

for $T \in [0, T_0]$.

Then the desired estimate (2.3) is an immediate consequence of (2.9). Thus the proof of Lemma 1 is completed.

We shall solve (1.5) by using Lemma 1 and the principle of contraction mappings. Define the iteration scheme $\{f_\varepsilon^N\}$ by

$$f_\varepsilon^0 = f_0,$$

$$\partial_t f_\varepsilon^{N+1} + \frac{1}{\varepsilon} \sum_{j=1}^N \nabla_j \partial_x f_\varepsilon^{N+1} + \frac{1}{\varepsilon^2} L f_\varepsilon^{N+1} = \frac{1}{\varepsilon} \Gamma (f_\varepsilon^N, f_\varepsilon^{N+1}),$$

$$f_\varepsilon^{N+1}(0, x) = f_0(x), \quad N = 0, 1, 2 \ldots$$

(2.10)

**Lemma 2.** Let $f_0 \in H^l$. Then suitable constants $T_0, k$ and $\lambda (\lambda < 1)$ exist such that for any $\varepsilon > 0$ and for any $t \in [0, T_0]$, the following estimates are satisfied:

$$\|f_\varepsilon^{N+1}\|_l \leq k,$$  

(2.11)

and

$$\|f_\varepsilon^{N+1} - f_\varepsilon^N\|_l \leq C_0 \lambda^\frac{n}{2}.$$  

(2.12)
Proof. Since \( \| f^0 \|_l = \| f_0 \|_l \leq k \), (2.11) follows thanks to Lemma 1.

Let \( h^N_\varepsilon = f^{N+1}_\varepsilon - f^N_\varepsilon \), therefore \( h^N_\varepsilon \) satisfy the equation:

\[
\partial_t h^N_\varepsilon + \frac{1}{\varepsilon} \sum_{j=1}^{n} V_j \partial_{x_j} h^N_\varepsilon + \frac{1}{\varepsilon^2} L f^N_\varepsilon = \frac{1}{\varepsilon} \left( \hat{\Gamma} \left( h^{N-1}_\varepsilon, f^{N+1}_\varepsilon \right) + \Gamma \left( f^{N-1}_\varepsilon, h^N_\varepsilon \right) \right).
\]

Applying the technique used in the proof of Lemma 1 one gets:

\[
\partial_t \left\| \hat{h}^N_\varepsilon \right\|_2^2 \leq \frac{1}{C} \left( \left\| \hat{\Gamma} \left( h^{N-1}_\varepsilon, f^{N+1}_\varepsilon \right) \right\|_2^2 + \left\| \hat{\Gamma} \left( f^{N-1}_\varepsilon, h^N_\varepsilon \right) \right\|_2^2 \right).
\]

Multiplying by \((1 + |\zeta|^2)^l\), integrating over \([0, T] \times \mathbb{R}^n\) and using (2.8). One can use again Plancherel’s Theorem (2.11) to deduce that:

\[
\left\| h^N_\varepsilon \right\|_l^2 \leq C k^2 T \left( \left\| h^{N-1}_\varepsilon \right\|_l^2 + \left\| h^N_\varepsilon \right\|_l^2 \right),
\]

with \( C = \frac{c_2^2}{cT} \).

Since \( C k^2 T < 1 \), it follows

\[
\left\| h^N_\varepsilon \right\|_l^2 \leq \frac{k^2 cT}{1 - k^2 cT} \left\| h^{N-1}_\varepsilon \right\|_l^2.
\]

Put

\[
\lambda = \frac{k^2 cT}{1 - k^2 cT}.
\]

It is clear that \( \lambda < 1 \) and (2.12) follows from (2.13).

\[
\quad
\]

2.2 Proof of Theorem 1

In view of Lemma 2 the estimates (2.11), (2.12) imply that for each \( \varepsilon > 0 \), \( \{ f^N_\varepsilon \} \) is a Cauchy sequence in \( L^\infty ([0, T], H^1) \). Let denote its limit by \( f_\varepsilon (t) \) and note that it satisfies the estimate (1.8), i.e., this limit in \( L^\infty ([0, T], H^1) \).

From (2.10) one sees that \( \partial_t f^{N+1}_\varepsilon \) can be expressed in terms of sequences converging in \( L^\infty ([0, T], H^{l-1}) \) as \( N \to +\infty \). The limit is

\[
H_\varepsilon = -\frac{1}{\varepsilon} \sum_{j=1}^{n} V_j \partial_{x_j} f_\varepsilon - \frac{1}{\varepsilon^2} L f_\varepsilon + \frac{1}{\varepsilon} \Gamma (f_\varepsilon, f_\varepsilon).
\]

Now let \( \Psi (t, x) \) be a \( C^\infty \) function of compact support in \([0, T] \times K\). We have just seen that

\[
\int_{[0, T] \times K} \langle \psi (t, x), \partial_t f^{N+1}_\varepsilon \rangle dt dx \to \int_{[0, T] \times K} \langle \psi (t, x), H_\varepsilon (t, x) \rangle dt dx,
\]

as \( N \to +\infty \). However

\[
\int_{[0, T] \times K} \langle \psi (t, x), \partial_t f^{N+1}_\varepsilon \rangle dt dx = - \int_{[0, T] \times K} \langle \partial_t \psi (t, x), f^{N+1}_\varepsilon \rangle dt dx
\]

\[
\to - \int_{[0, T] \times K} \langle \partial_t \psi (t, x), f_\varepsilon \rangle dt dx,
\]

as \( N \to +\infty \).
as $N \to +\infty$. Therefore $H_\varepsilon(t)$ is identified with the distributions derivative in $t$ of $f_\varepsilon$. It follows that $f_\varepsilon$ satisfies the equation (1.5) and moreover $\frac{\partial f_\varepsilon}{\partial t} \in L^\infty([0,T], H^{1-1})$; hence $f_\varepsilon \in C([0,T], H^{1-1})$. X-Mozilla-Status: 0000

3 Hydrodynamical limit

This section deals with the strong convergence of the solution of the discrete velocity model (1.1) towards solution of the nonlinear incompressible Navier–Stokes equations (1.11)–(1.12). In order to derive the hydrodynamical limit, some uniform regularity estimates would likely be needed for obtaining the limit of the nonlinear terms.

3.1 Strong convergence

To prove Theorem 2, one needs more than the uniform bound (1.8) for $f_\varepsilon$. For this purpose we assume that hypothesis (1.9) holds and we show the uniform bound for $\frac{\partial f_\varepsilon}{\partial t}$.

The uniform equicontinuity in $t$ is given by the following:

**Lemma 3.** Assume that hypothesis (1.9) holds and let $l > \frac{n}{2} + 1$. Then

$$\left\| \frac{df_\varepsilon}{dt} \right\|_{l-1} \leq C \exp \left( \frac{C k^2 T}{2} \right), \quad \forall t \in [0,T], \quad \varepsilon \in (0,1),$$

(3.1)

where the constant $C$ does not depend on $\varepsilon$.

**Proof.** By differentiating the equation (1.5) with respect to $t$ and by taking the Fourier transform of the equation obtained, one has

$$\frac{d}{dt} \hat{f}_\varepsilon + \frac{1}{\varepsilon} \sum_{j=1}^n i \zeta_j V_j \hat{\partial_t \hat{f}_\varepsilon} + \frac{1}{\varepsilon^2} L \hat{\partial_t \hat{f}_\varepsilon} = \frac{1}{\varepsilon^2} \hat{\partial_t \hat{\Gamma}(f_\varepsilon, f_\varepsilon)}.$$  

(3.2)

Taking the inner product (in $C^m$) of (3.2) with $\partial_t \hat{f}_\varepsilon$. The real part of the resulting equality is

$$\frac{\partial_t |\partial_t \hat{f}_\varepsilon|^2}{2} + \frac{1}{\varepsilon^2} \langle L \hat{\partial_t \hat{f}_\varepsilon}, \partial_t \hat{f} \rangle = \frac{1}{\varepsilon} \Re \langle \hat{\Gamma}(\partial_t f, f), \partial_t \hat{f} \rangle.$$  

Since $L$ is positive semi-definite and $\Gamma \in N(L)^\perp$, we get

$$\frac{\partial_t |\partial_t \hat{f}_\varepsilon|^2}{2} + \frac{C_1}{\varepsilon^2} |P^\perp \partial_t \hat{f}_\varepsilon|^2 \leq \frac{1}{\varepsilon} \|\hat{\Gamma}(\partial_t f_\varepsilon, f_\varepsilon)\| |P^\perp \partial_t \hat{f}_\varepsilon| \leq \frac{1}{2C_1} \|\hat{\Gamma}(\partial_t f_\varepsilon, f_\varepsilon)\|^2 + \frac{C_1}{2\varepsilon^2} |P^\perp \partial_t \hat{f}_\varepsilon|^2.$$  

So, multiplying by $(1 + |\zeta|^2)^{l-1}$, integrating over $\mathbb{R}_\zeta^n$ and using (2.8) one gets

$$\partial_t \|\partial_t f_\varepsilon\|_{l-1}^{l-1} \leq \frac{1}{C_1} \|\hat{\Gamma}(\partial_t f_\varepsilon, f_\varepsilon)\|_{l-1}^{l-1} \leq C \|\partial_t f_\varepsilon\|_{l-1}^{l-1} \|f_\varepsilon\|_{l-1}^{l-1}.$$  

(3.3)
Using Gronwall’s inequality, one reduces (3.3) to
\[ \| \partial_t f_\varepsilon \|_{l^{-1}} \leq \exp \left( \frac{Ck^2T}{2} \right) \| \partial_t f_\varepsilon(0) \|_{l^{-1}}. \]

By using equation (1.5) in order to express \( \partial_t f_\varepsilon(0) \) in terms of the initial data we have
\[ \| \partial_t f_\varepsilon \|_{l^{-1}} \leq \exp \left( \frac{Ck^2T}{2} \right) \left( \frac{1}{\varepsilon} \left\| \sum_{j=1}^{n} V^j \partial_{x_j} f_0 \right\|_{l^{-1}} + \frac{1}{\varepsilon^2} \| Lf_0 \|_{l^{-1}} + \frac{1}{\varepsilon} \| \Gamma(f_0, f_0) \|_{l^{-1}} \right). \]

Taking into account hypothesis (1.9), one gets
\[ \| \partial_t f_\varepsilon \|_{l^{-1}} \leq C \exp \left( \frac{Ck^2T}{2} \right) \left( \frac{1}{\varepsilon^2} \left\| \sum_{j=1}^{n} V^j \partial_{x_j} f_0 \right\|_{l^{-1}} + \frac{1}{\varepsilon^2} \| Lf_0 \|_{l^{-1}} + \frac{1}{\varepsilon^3} \| k_\varepsilon \|_t^2 + \frac{1}{\varepsilon} \| \Gamma(h_\varepsilon, h_\varepsilon) \|_{l^{-1}} \right) \leq C \exp \left( \frac{Ck^2T}{2} \right). \]

The proof of (3.1) is now complete. \[ \blacksquare \]

**Conclusion.** From Lemma 3 we conclude the following: the solution \( f_\varepsilon \) is bounded in \( C([0, T], H^{l-1}) \), uniformly for \( \varepsilon > 0 \), for \( t \) in any compact subset of the interval \([0, T]\), moreover \( f_\varepsilon \) satisfies the bound (3.1). Therefore by the Ascoli–Arzela lemma we can choose a convergent subsequence \( f_{\varepsilon_j} \), where \( \varepsilon_j \to 0 \) such that
\[ f_{\varepsilon_j} \to f \quad \text{in} \quad C \left( [0, T], H^{l-1} \right). \] \[ (3.4) \]
and the limit function satisfies the bound (1.6).

Thanks to convergence results (3.4), the estimate (1.8) allow us to deduce (possibly taking subsequences) the following convergence
\[ \Gamma(f_{\varepsilon_j}, f_{\varepsilon_j}) \to \Gamma(f, f) \quad \text{strongly in} \quad H^{l-1}. \] \[ (3.5) \]

### 3.2 Passage to the limit

This subsection is devoted to the connection between the discrete velocity kinetic equations (1.1) and the incompressible Navier–Stokes equations (1.11)–(1.12), we use the techniques described in [3]. In order to get these equations, one needs the following:

**Lemma 4.** Let \( f, g \in \mathbb{R}^m \). One gets
\[ \langle f, Lg \rangle = \frac{1}{8} \sum_{i,j,k,l} A_{kl}^{ij} (M_i M_j + M_k M_l) (f_i^* + f_j^* - f_k^* - f_l^*) (g_i^* + g_j^* - g_k^* - g_l^*), \] \[ (3.6) \]
where
\[ f_i^* = \frac{f_i}{\sqrt{\alpha_i M_i}}, \quad i = 1, \ldots, m. \]

**Proof.** See [7] and [23]. \[ \blacksquare \]
Lemma 5. Let $f \in N(L)$. One has
\[
\Gamma(f, f) = \frac{1}{2} L \left( \frac{f^2}{\alpha M} \right). \tag{3.7}
\]

Proof. Using (1.7), one gets
\[
\Gamma(f, f) = \Lambda^{-\frac{1}{2}} \left( \frac{1}{\alpha_i} \sum_{j,k,l} \left( A_{kl}^{ij} \sqrt{M_k M_l} f_k f_l - A_{kl}^{kj} \sqrt{M_l M_j} f_l f_j \right) \right)
= \left( \sum_{j,k,l} \left( A_{kl}^{ij} \frac{\sqrt{M_k M_l}}{\sqrt{\alpha_i \alpha_k \alpha_l M_i}} f_k f_l - A_{kl}^{kj} \frac{\sqrt{M_l M_j}}{\sqrt{\alpha_i \alpha_k \alpha_j M_i}} f_l f_j \right) \right). \tag{3.8}
\]

On the other hand, if $f \in N(L)$, so one gets by (3.6) the following identity:
\[
A_{kl}^{ij} \left( \frac{f_i}{\sqrt{\alpha_i M_i}} + \frac{f_j}{\sqrt{\alpha_j M_j}} - \frac{f_l}{\sqrt{\alpha_l M_l}} - \frac{f_k}{\sqrt{\alpha_k M_k}} \right) = 0, \quad \forall \ i, j, k, l.
\]
Thus, we have
\[
2 A_{kl}^{ij} \frac{f_i f_j}{\sqrt{\alpha_i \alpha_j \alpha_k M_i M_j}} = A_{kl}^{ij} \left( \frac{f_i^2}{\alpha_i M_i} + \frac{f_j^2}{\alpha_j M_j} - \frac{f_l^2}{\alpha_l M_l} - \frac{f_k^2}{\alpha_k M_k} + \frac{2 f_i f_k}{\alpha_i \alpha_k M_i M_k} \right).
\]

Hence substituting this identity into (3.8) yields:
\[
\Gamma(f, f) = \left( \sum_{j,k,l} A_{kl}^{ij} \left( \frac{\sqrt{M_k M_l}}{\sqrt{\alpha_i \alpha_k \alpha_l M_i}} f_k f_l - \frac{\sqrt{M_l M_j}}{\sqrt{\alpha_i \alpha_l \alpha_k M_l}} f_l f_j - \frac{1}{2} \frac{\sqrt{M_i M_j}}{\alpha_i \alpha_l M_i} f_i^2 \right.ight.
- \left. \frac{1}{2} \frac{\sqrt{M_i M_j}}{\alpha_i \alpha_k M_k} f_k^2 + \frac{1}{2} \frac{\sqrt{M_i M_j}}{\alpha_j \alpha_l M_j} f_j^2 + \frac{1}{2} \frac{\sqrt{M_i M_j}}{\alpha_j \alpha_k M_k} f_j^2 \right) \right). \tag{3.9}
\]

Noting that
\[
A_{kl}^{ij}(M_i M_j - M_k M_l) = 0, \quad \forall \ i, j, k, l.
\]
So,
\[
A_{kl}^{ij} \left( \frac{\sqrt{M_k M_l}}{\sqrt{\alpha_i \alpha_k \alpha_l M_i}} f_k f_l - \frac{\sqrt{M_l M_j}}{\sqrt{\alpha_i \alpha_l \alpha_k M_l}} f_l f_j \right) = 0,
\]
which with (3.9) imply
\[
\Gamma(f, f) = -\frac{1}{2} \left( \sum_{j,k,l} A_{kl}^{ij} \left( \frac{\sqrt{M_i M_j}}{\sqrt{\alpha_i \alpha_k \alpha_l M_i}} f_k^2 + \frac{\sqrt{M_l M_j}}{\sqrt{\alpha_i \alpha_l \alpha_k M_l}} f_i^2 - \frac{\sqrt{M_i M_j}}{\alpha_i \sqrt{\alpha_l M_i}} f_i^2 - \frac{\sqrt{M_i M_j}}{\alpha_j \sqrt{\alpha_l M_l}} f_j^2 \right) \right) \right). \tag{3.10}
\]

Therefore the desired identity (3.7) follows from (3.10) and (1.6).
**Lemma 6.** Let \( \chi \) be a test function such that
\[
\sum_{j=1}^{n} \sum_{r=1}^{d} \partial_{x_j} \chi r \langle e_r, V^j e_l \rangle = 0, \quad l = 1, \ldots, d. \tag{3.11}
\]

Then
\[
\langle \sum_{j=1}^{n} \partial_{x_j} \langle f_\varepsilon, P(V^j (e_l)) \rangle, \chi \rangle = 0, \quad l = 1, \ldots, d, \tag{3.12}
\]

where \( P \) is the projection onto \( N(L) \).

**Proof.** One has
\[
\langle \sum_{j=1}^{n} \partial_{x_j} \langle f_\varepsilon, P(V^j (e_l)) \rangle, \chi \rangle = \langle \sum_{j=1}^{n} \partial_{x_j} \langle P f_\varepsilon, V^j (e_l) \rangle, \chi \rangle = \sum_{j=1}^{n} \sum_{r=1}^{d} \langle \partial_{x_j} \alpha_{\varepsilon, r} \langle e_r, V^j (e_l) \rangle, \partial_{x_j} \chi_l \rangle = 0.
\]

Integrating by parts and using (3.5), one gets
\[
\langle \sum_{j=1}^{n} \partial_{x_j} \langle f_\varepsilon, P(V^j (e_l)) \rangle, \chi \rangle = - \sum_{j=1}^{n} \sum_{r=1}^{d} \langle \alpha_{\varepsilon, r} \langle e_r, V^j (e_l) \rangle, \partial_{x_j} \chi_l \rangle = 0.
\]

This ends the proof of Lemma 6. \[\blacksquare\]

**Completion of the proof.** Multiplying the equation (1.5) by \( \varepsilon^2 \), letting \( \varepsilon \) go to zero and using (3.4), yields the relation
\[
Lf = 0.
\]

This implies that \( f \in N(L) \) and thus can be written according to the formula (1.10).

The scaled local conservation laws associated with the kinetic equation (1.5) are
\[
\partial_t \langle f_\varepsilon, e_i \rangle + \frac{1}{\varepsilon} \sum_{j=1}^{n} \partial_{x_j} \langle V^j f_\varepsilon, e_i \rangle = 0, \quad i = 1, \ldots, d. \tag{3.13}
\]

Letting \( \varepsilon \) tend to zero and applying formula (1.8) yields condition (1.11).

As was done in [3] for the classical continuous Boltzmann equation, we divide by \( \varepsilon \) and we decompose the flux in the form
\[
\partial_t \langle f_\varepsilon, e_i \rangle + \frac{1}{\varepsilon} \sum_{j=1}^{n} \partial_{x_j} \langle f_\varepsilon, P(V^j e_i) \rangle + \frac{1}{\varepsilon} \sum_{j=1}^{n} \partial_{x_j} \langle f_\varepsilon, P(V^j e_i) \rangle = 0. \tag{3.14}
\]

Using 3.11 (Lemma 6), the second term of (3.14) can be eliminated upon integrating (3.14) against test functions satisfying (3.11).
The limit of the first flux term in (3.14) is computed using the fact that $P^\perp(V^j e_i) \in \text{Ran}(L)$ along with the kinetic equation (1.5) to obtain

$$
\partial_t (f_\varepsilon, e_i) + \sum_{j=1}^{n} \partial_{x_j} \langle -\varepsilon \partial_t f_\varepsilon - \sum_{k=1}^{n} V^k \partial_{x_k} f_\varepsilon + \Gamma(f_\varepsilon, f_\varepsilon), L^{-1} P^\perp(V^j e_i) \rangle \\
+ \frac{1}{\varepsilon} \sum_{j=1}^{n} \partial_{x_j} \langle f_\varepsilon, P(V^j e_i) \rangle = 0, \quad i = 1, \ldots, d.
$$

(3.15)

Letting $\varepsilon$ goes to zero,

$$
\sum_{j=1}^{n} \sum_{k=1}^{n} \partial_{x_j} \partial_{x_k} \langle V^k f_\varepsilon, L^{-1}(P^\perp(V^j e_i)) \rangle \to \sum_{j=1}^{n} \sum_{k=1}^{n} \partial_{x_j} \partial_{x_k} \langle V^k \rho \cdot e, L^{-1}(P^\perp(V^j e_i)) \rangle

= \nabla^2 : (Ve \otimes L^{-1}(P^\perp(Ve)))\rho,
$$

(3.16)

in $D'_{t,x}$.

The limiting quadratic term of (3.15) must be evaluated further in order to bring it into the form that appears in (1.12). Since $f \in N(L)$ the convergence (3.5) and the identity (3.7) can be employed to show the following convergence in $D'_{t,x}$ as $\varepsilon \to 0$,

$$
\sum_{j=1}^{n} \partial_{x_j} \langle \Gamma(f_\varepsilon, f_\varepsilon), L^{-1}(P^\perp(V^j e_i)) \rangle \to \sum_{j=1}^{n} \partial_{x_j} \langle \Gamma(f, f), L^{-1}(P^\perp(V^j e_i)) \rangle

= \frac{1}{2} \sum_{j=1}^{n} \partial_{x_j} \langle \frac{(\rho \cdot e)^2}{\sqrt{\alpha M}} P^\perp(V^j e_i) \rangle = \frac{1}{2} \nabla \cdot (P^\perp(Ve), \frac{(\rho \cdot e)^2}{\sqrt{\alpha M}}).
$$

(3.17)

Passing to the limit $\varepsilon \to 0$ in equation (3.15), the above convergence (3.16) and (3.17) suffices to write the limit equation (1.12).

By integrating the equation (3.15) over $t$, we have

$$
\langle f_\varepsilon, e_i \rangle - \langle f_\varepsilon(0), e_i \rangle

= -\int_0^t \left( \sum_{j=1}^{n} \partial_{x_j} \langle -\varepsilon \partial_t f_\varepsilon - \sum_{k=1}^{n} V^k \partial_{x_k} f_\varepsilon + \Gamma(f_\varepsilon, f_\varepsilon), L^{-1} P^\perp(V^j e_i) \rangle \\
+ \frac{1}{\varepsilon} \sum_{j=1}^{n} \partial_{x_j} \langle f_\varepsilon, P(V^j e_i) \rangle(s) \right) ds = 0, \quad i = 1, \ldots, d.
$$

Let $\varepsilon \to 0$ and putting $t = 0$, it follows

$$
\langle f, e_i \rangle(0) = \langle h, e_i \rangle.
$$

(3.18)

Therefore the desired initial condition for the system (1.12) follows from (3.18).

In the next, we will apply the results discussed in Section 1 to two examples.
4 Example, I (Carleman model)

The simplest one-dimensional discrete-velocity models of the Boltzmann equation are certainly those with two velocities. These models describe the evolution of the velocity distribution of a fictitious gas composed of two kinds of particles that move parallel to the $x$-axis with constant speed equal to one, either in the positive $x$-direction with a density $F_1$, or in the negative $x$-direction with a density $F_2$. The corresponding dimensionless hyperbolic system is given by (see [20]):

\[
\begin{align*}
\varepsilon \frac{dF_1^\varepsilon}{dt} + \frac{dF_1^\varepsilon}{dx} &= \frac{1}{\varepsilon} (F_2^\varepsilon - F_1^\varepsilon), \\
\varepsilon \frac{dF_2^\varepsilon}{dt} - \frac{dF_2^\varepsilon}{dx} &= \frac{1}{\varepsilon} (F_1^\varepsilon - F_2^\varepsilon), \\
F_i^\varepsilon(t = 0, x) &= F_i^0, \quad i = 1, 2.
\end{align*}
\]

Here we have $(\alpha_1, \alpha_2) = (1, 1)$ and

\[A_{11}^{22} = A_{22}^{11} = 1, \quad \text{and} \quad A_{kl}^{ij} = 0 \text{ otherwise.}\]

The condition (1.3) is satisfied. The space $M$ of summational invariants consists of vectors $\phi = t(\phi_1, \phi_2)$ satisfying $\phi_1 - \phi_2 = 0$. Therefore $M$ is spanned by $\phi = (1, 1)$.

On the other hand a locally Maxwellian state is a vector $F = t(F_1, F_2) > 0$ satisfying $F_2^2 = F_1^2$. Let $M = (1, 1)$ be an absolute Maxwellian state: $M = (1, 1)$. Set $F(t, x) = M + \varepsilon \Lambda \frac{1}{2} f(t, x)$, here $\Lambda = I_d$, and substitute it into (4.1), we get:

\[
\begin{align*}
\partial_t f_\varepsilon + \frac{1}{\varepsilon} \partial_x V f_\varepsilon + \frac{1}{\varepsilon^2} L f_\varepsilon &= \frac{1}{\varepsilon} \Gamma(f_\varepsilon, f_\varepsilon), \\
f_\varepsilon(t = 0, x) &= f_0(x),
\end{align*}
\]

where

\[
L = 2 \left( \begin{array}{cc}
1 & -1 \\
1 & 1
\end{array} \right), \quad V = \left( \begin{array}{cc}
1 & 0 \\
0 & -1
\end{array} \right),
\]

and

\[
\Gamma(f, f) = (f_1^2 - f_2^2) t_{(-1, 1)}.
\]

As $\varepsilon \to 0$, we get that $f_\varepsilon \to f$ in $D'_{t,x}$ (distribution sense) with $f = \rho \cdot e$ and $\rho$ is solution of the heat equation:

\[
\partial_t \rho = \frac{1}{4} \partial_x^2 \rho.
\]

It follows from the uniqueness of the solution of the initial value problem for (4.3) that all sequences of $f_\varepsilon$ as $\varepsilon \to 0$ give the same system (4.3) in the limit.

Thus we have proved

**Theorem 4.** Let $f_0 \in H^1(\mathbb{R})$, then there exists a positive constants $T_0$ and $k$ (depending only on $\|f_0\|_{l_1}$) such that the initial value problem (4.2) has a unique solution $f_\varepsilon \in L^\infty([0, T_0], H^1(\mathbb{R})) \cap C([0, T], L^2(\mathbb{R}))$ satisfying

\[
\|f_\varepsilon(t)\|_{l_1} \leq k,
\]

for $t \in [0, T_0]$. 
If in addition $f_0$ satisfies
\[ f_\varepsilon(0) = t(h_\varepsilon, h_\varepsilon) + \varepsilon^2 k_\varepsilon, \quad \|\partial_\varepsilon h_\varepsilon\|_2 \leq C \varepsilon, \quad \lim_{\varepsilon \to 0} \|h_\varepsilon - h\|_2 = 0, \quad (4.5) \]
we get

**Theorem 5.** As $\varepsilon \to 0$, $f_\varepsilon \to f = \rho \cdot v$ weakly in $L^\infty([0,T_0], H^1)$ and strongly in $C([0,T], L^2(x))$ and the limit satisfies the heat equation:
\[ \partial_t \rho = \frac{1}{4} \partial_\varepsilon^2 \rho, \quad \rho(0, x) = \langle h, e \rangle. \quad (4.6) \]

## 5 Example, II (Broadwell model)

We shall first describe the six-velocity model gas considered by Broadwell [17] and in [29] and then specialize it to one dimension. We consider the following equation:
\[ \varepsilon \frac{dF_i}{dt} + \frac{dF_i}{dx} = \frac{B}{3\varepsilon} (F_{i+1}F_{i+4} + F_{i+2}F_{i+5} - 2F_iF_{i+3}), \quad i = 0, \ldots, 5 \quad (5.1) \]
Here $F_i$ are the densities of the particles with velocity
\[ u_i = \left(c \cos \left(\theta + i \frac{\pi}{3}\right), c \sin \left(\theta + i \frac{\pi}{3}\right)\right), \]
and $B$ denotes the collision frequency.

We specialize (5.1) to solutions that do not depend on $y$, and $\theta = 0$, and such that $F_5 = F_1$ and $F_4 = F_2$. We can write (5.1) for $F_1, F_2, F_3$ and $F_4$:
\[ \varepsilon \frac{dF_0}{dt} + \frac{dF_0}{dx} = \frac{2B}{3\varepsilon} (F_1F_2 - F_0F_3), \]
\[ \varepsilon \frac{F_1}{dt} + \frac{1}{2} \frac{dF_1}{dx} = \frac{B}{3\varepsilon} (F_0F_3 - F_1F_2), \]
\[ \varepsilon \frac{dF_2}{dt} - \frac{1}{2} \frac{dF_2}{dx} = \frac{B}{3\varepsilon} (F_0F_3 - F_1F_2), \]
\[ \varepsilon \frac{dF_3}{dt} - \frac{dF_3}{dx} = \frac{2B}{3\varepsilon} (F_1F_2 - F_0F_3). \quad (5.2) \]

By the form of second member we have $(\alpha_0, \alpha_1, \alpha_2, \alpha_3) = \left(\frac{1}{2}, 1, 1, \frac{1}{2}\right)$ and the relation (1,3) is satisfied. To get the equation (1.11)–(1.12) for the Broadwell’s model we need some preparations. The space $\mathcal{M}$ of summational invariants consists of vectors $\phi = t(\phi_1, \phi_2, \phi_3, \phi_4)$ satisfying $2\phi_1 + 2\phi_4 = \phi_2 + \phi_3$. Therefore $\mathcal{M}$ is spanned by $\{\phi_1, \phi_2, \phi_3\}$, where
\[ \phi_1 = t(1, 0, 0, -1), \quad \phi_2 = t(0, 1, 0, \frac{1}{2}), \quad \phi_3 = t(0, 0, 1, \frac{1}{2}) \]

On the other hand a locally Maxwellian state is a vector $F = t(F_0, F_1, F_2, F_3) > 0$ satisfying $F_2F_1 = F_0F_3$. Let $M = t(1,1,1,1)$ be an absolute Maxwellian state. Set $F(t, x) = M + \Lambda^{\frac{1}{2}} f(t, x)$ for $\Lambda = \text{diag}(2, 1, 1, 2)$ and substitute it into (5.2):
\[ f_t + \frac{V f x}{\varepsilon} + \frac{L f}{\varepsilon^2} = \frac{1}{\varepsilon} \Gamma(f, f), \]
\[ f(t = 0, x) = f_0(x), \quad (5.3) \]
where \( V = \text{diag} \left( 1, \frac{1}{2}, -\frac{1}{2}, -1 \right) \) and
\[
L = -\frac{B}{3} \begin{pmatrix}
-2 & \sqrt{2} & \sqrt{2} & -2 \\
\sqrt{2} & -1 & -1 & \sqrt{2} \\
\sqrt{2} & -1 & -1 & \sqrt{2} \\
-2 & \sqrt{2} & \sqrt{2} & -2
\end{pmatrix},
\]
\[
\Gamma(f, f) = \frac{B}{3} (f_2 f_1 - 2 f_0 f_3) t(\sqrt{2}, -1, -1, \sqrt{2}).
\]

Since \( N(L) = \Lambda^\frac{1}{2} M \), a simple calculations gives the orthonormal basis \( \{e_i, i = 1, 2, 3\} \) for \( N(L) \):
\[
e_1 = t \left( \frac{\sqrt{2}}{2}, 0, 0, -\frac{\sqrt{2}}{2} \right), \quad e_2 = t \left( \frac{\sqrt{5}}{10}, \frac{\sqrt{5}}{5}, 0, \frac{\sqrt{5}}{5} \right), \quad e_3 = t \left( \frac{\sqrt{3}}{\sqrt{10}}, -\frac{\sqrt{3}}{\sqrt{10}}, \frac{\sqrt{3}}{\sqrt{5}}, \frac{\sqrt{3}}{\sqrt{5}} \right).
\]

By letting \( \varepsilon \to 0 \) in (5.3) and using the results of Section 1, we get \( f_\varepsilon \to f \) in \( D_{t,x}' \) (distribution sense) with \( f = \rho \cdot e \), where
\[
\rho = t(\rho_1, \rho_2, \rho_3), \quad e = t(e_1, e_2, e_3),
\]
and from (1.9) we get
\[
\rho_3 = \frac{2\sqrt{3}}{\sqrt{10}} \rho_1, \quad \rho_2 = -\frac{2}{\sqrt{5}} \rho_1.
\]

**Lemma 7.** Let \( f = \rho \cdot e \) satisfying (5.6), then
\[
\Gamma(f, f) = 0,
\]
\[
\langle V f, h \rangle = 0 \quad \text{for any} \quad h \in N(L).
\]

**Proof.** By using (5.5) and (5.6), we get (5.7). (5.8) is obtained by a direct calculations. This completes the proof. \( \blacksquare \)

**Lemma 8.** Let \( f = \rho \cdot e \) satisfying (5.6), then
\[
\langle L^{-1}(P^\perp(V e_1)), V f \rangle = \frac{\rho_1}{2B},
\]
\[
\langle L^{-1}(P^\perp(V e_2)), V f \rangle = -\frac{\rho_1}{4B\sqrt{5}},
\]
\[
\langle L^{-1}(P^\perp(V e_3)), V f \rangle = \frac{\sqrt{6} \rho_1}{8B\sqrt{5}}.
\]

**Proof.** The proof of this lemma follows from Lemma 7. \( \blacksquare \)

Using the results of Section 1 combined with Lemma 8, one gets:

**Theorem 6.** Let \( f_0 \in H^1(\mathbb{R}) \), then there exists a positive constants \( T_0 \) and \( k \) (depending only on \( \|f_0\|_1 \)) such that the initial value problem (5.3) has a unique solution \( f_\varepsilon \in L^\infty \left( [0, T_0], H^1(\mathbb{R}) \right) \cap C \left( [0, T], L^2(\mathbb{R}) \right) \) satisfying
\[
\|f_\varepsilon(t)\|_1 \leq k, \quad \text{for} \quad t \in [0, T_0].
\]
If in addition the initial condition satisfies:

\[
\begin{align*}
  f_\varepsilon(0) &= h_\varepsilon + \varepsilon^2 k_\varepsilon, \\
  L h_\varepsilon &= 0, \\
  \|\partial_x h_\varepsilon\|_2 &\leq C\varepsilon, \\
  \lim_{\varepsilon \to 0} \|h_\varepsilon - h\|_2 &= 0,
\end{align*}
\]  

(5.13)

one gets:

**Theorem 7.** As \( \varepsilon \to 0 \), \( f_\varepsilon \to f = \rho \cdot e \) weakly in \( L^\infty([0,T_0],H^1) \) and strongly in \( C([0,T],L^2(x)) \) and the limit satisfies the heat equation:

\[
\begin{align*}
  \partial_t \rho_1 &= \frac{1}{4B} \partial_x^2 \rho_1, \\
  \rho_3 &= \frac{2\sqrt{3}}{\sqrt{10}} \rho_1, \\
  \rho_2 &= -\frac{2}{\sqrt{5}} \rho_1, \\
  \rho_1(t = 0) &= \rho_{10} - \frac{2}{\sqrt{5}} \rho_{20} + 2 \frac{\sqrt{3}}{\sqrt{10}} \rho_{30}
\end{align*}
\]

(5.14)

where

\[
\rho_i = \langle h, e_i \rangle, \quad i = 1, 2, 3.
\]

**Remark 5.** One can remove the assumption \( \|\Gamma(h_\varepsilon, h_\varepsilon)\|_2 \leq C\varepsilon \) in (5.13). A price to be paid for this improvement is that: we see the solution of (5.2) in the form \( F_\varepsilon = M + \varepsilon \phi(\varepsilon)f_\varepsilon \) with \( \phi(\varepsilon) = O(\varepsilon) \) (see [12]).
